METHODOLOGY CLARIFICATION - FINAL V2

Group 19 / Seoul Ttareungi / Revised 17 October 2026

Normal-day definition

A normal day is a station-day with no hourly snapshot showing zero available bikes. Demand uses the station's average on normal days of the same weekpart (at least 3 days), else its average on all normal days (at least 5), else a regression estimate (630 rows).

Correlation units

District-level equity check: Spearman rank correlation between district net move and district demand per station is 0.05 on weekdays and -0.06 on weekends.
Station-level model summary: Spearman correlation between station move and predicted demand is +0.054 on weekdays and +0.0043 on weekends. These statistics use different aggregation units and are not contradictory.

Interpretation

The original hypothesis concerns effective demand, including unmet requests. Predicted demand is a proxy, so the station-level regression and redistribution scenario are exploratory association and planning results, not causal evidence.
